1.0 Executive Summary

Inflation is an increase in the level of prices of goods and services in an economy over a period of time. The City of Edmonton monitors inflation as it can have various effects on its year-to-year operations and financial decision-making that is tied to the City's budgetary process.

Consumer inflation is typically measured through the Consumer Price Index (CPI) produced by Statistics Canada. The CPI represents the purchasing patterns of an average consumer and is a generally accepted measure of inflation. The CPI, however, is not the best tool to assess inflationary pressures the City of Edmonton faces because it does not adequately represent the municipal purchasing patterns.

The Municipal Price Index (MPI) serves to measure inflation for the City of Edmonton and reflects the mix of goods and services purchased by the City of Edmonton. Development of an MPI was undertaken as a means to measure inflation the City of Edmonton's operating budget faces.

Following the 2009 recession, the provincial economy along with the Edmonton economy expanded rapidly. During this post-recession period municipal inflation fluctuated between 2% and 4% from 2010 to 2015. With the exception of 2014, municipal inflation has been consistently higher than consumer inflation by 0.70–2.59%.

At the time of the last MPI report, the estimated 2015 MPI for the City was 0.44% while the expected CPI was 1.85%. The actual year-end MPI was higher than the estimated value and stood at 1.39% in 2015. The actual CPI for 2015 stood at 1.22%, which was lower than the estimated value mainly due to decreased energy, natural gas and transportation costs when compared to 2014.

In 2016, municipal inflation is forecasted to be 1.91% while the consumer inflation is estimated to be 1.84%.

The MPI is forecasted to continue to trend upward mainly due to higher oil and natural gas prices. In 2017, municipal inflation is estimated to be 2.55%, 2.78% in 2018, 2.89% in 2019 and 3.06% in 2020. Consumer inflation is estimated to be in the 1.84% to 2.48% range over the same period.

The table below displays the actual MPI and CPI from 2010 to 2015 along with forecast for 2016–2020.¹

Comparison of Municipal and Consumer Inflation Rates 2010–2020

	Actual						Forecast				
	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020
Municipal Inflation	3.64%	3.21%	2.87%	2.99%	2.07%	1.39%	1.91%	2.55%	2.78%	2.89%	3.06%
Consumer Inflation ²	1.05%	2.52%	1.18%	1.21%	2.34%	1.22%	1.84%	2.09%	2.11%	2.48%	2.06%
Difference	2.59%	0.70%	1.70%	1.78%	-0.27%	0.17%	0.07%	0.46%	0.67%	0.41%	1.00%

¹ The actual MPI figures from 2010 to 2013 were revised to reflect the new expenditure weights based on the City's 2014 operating budget.

2.0 Introduction

2.1 Understanding Inflation

Inflation is defined as the rise in the level of prices of goods and services in an economy over a period of time and is measured as an annual percentage increase in the Consumer Price Index (CPI). In essence, inflation means that every unit of currency buys a smaller amount of goods and services over time. An upward trend in inflation causes a decline in the purchasing power of money. For example, if an item costs \$100.00 in period 1 and period-to-period inflation is 2%, that same item will cost \$102.00 in period 2, cost \$104.04 in period 3 and so forth.

Since 1991, the Bank of Canada has employed an inflation control target that aims to maintain annual consumer inflation at 2%—the mid-point of a control range of 1% to 3%. This inflation-targeting approach to monetary policy guides the Bank of Canada in maintaining a stable price environment over the medium term. As a result, consumer inflation as measured by the CPI has been, on average, stable at the national level.

The City of Edmonton's cost of municipal service provision also faces inflation. Due to price increases, a larger amount of expenditure is required in the City's operating budget to purchase the same mix of goods and services over time. However, because the City purchases a considerably different range of goods and services than the average Canadian consumer, the CPI is not an adequate measure of the inflation the City' operating budget experiences. Moreover, municipal costs tend to experience a higher level of inflation than average consumer costs do. Thus, a Municipal Price Index (MPI) was developed to measure the price increases the City of Edmonton's operating budget faces.

The development of the MPI necessitated the formation of steering and working committees. The steering committee comprises senior managers from the Financial and Corporate Services Department who provide direction and assign resources to the project. The working committee, that comprises representatives from most sections of the Financial and Corporate Services Department, provided direction on the composition of expenditure categories, weights and inflation factors. The City of Edmonton's MPI was also created in accordance with *The Way We Finance*, with both projects developed in close alignment.

The MPI is not a prescriptive tool that mandates operating budget expenditures to increase by a designated amount each year. Rather, the MPI is a tool that helps better inform the City's budgetary process of external economic conditions that the City will face.

3.0 Consumer Price Index versus Municipal Price Index

The Consumer Price Index (CPI) is a measure of the price changes experienced by Canadians. Produced by Statistics Canada, the CPI is calculated by comparing the cost of a fixed basket of goods and services bought by an average Canadian consumer over time. Since the basket consists of goods and services of equivalent quality or quantity, the index reflects only the price change. The CPI is the most widely used calculation of inflation for Canada, the provinces and municipalities.

The goods and services included in the CPI are grouped if they have similar end-uses, or are deemed substitutes for one another. These groups of products are joined together at different levels, and the highest level of grouping is called a major component. The major components that comprise the CPI basket of goods and services are the following: food; shelter; household operations, furnishings and equipment; clothing and footwear; transportation; health and personal care; recreation, education and reading; and alcoholic beverages and tobacco products.³

Major components of the CPI basket are attributed a weight in relation to spending trends by Canadian consumers. For example, the proportion of total basket that each major component comprises is based on the proportion of total consumer expenditures made on those goods and services. These proportions signify the relative importance, or weight, of a grouping of products in the basket.

The content of the CPI basket is reviewed and updated by Statistic Canada every two years to ensure that the basket of goods and services included in the CPI remains relevant. The weights of each major component are updated to reflect the spending patterns obtained from the Survey of Household Spending from a more recent period. Figure 1 shows the major CPI components and their respective weights for Canada, based on consumer spending in 2013.⁴

The weight attributed to each major component determines the impact that a specific price change will have on the overall consumer budget. In the 2013 basket, the weight assigned to shelter was 26.80% whereas the weight assigned to clothing and footwear was 6.08%. This means that, a 10% increase in the price of shelter will have a much greater impact on the

³ Statistics Canada. 1996. *Your Guide to the Consumer Price Index*. Catalogue no. 62-557-XPB.

⁴ The 2013 basket is the most recent update to the CPI basket and was published on March 20, 2015.

average consumer budget than a 10% increase in the price of clothing and footwear. In an absence of weights, all goods and services would be given an equivalent degree of importance, which does not accurately represent the average consumer's expenditure basket.

Figure 1: 2013 CPI Weights of Major Components – Canada ⁵

The CPI is a useful indicator of inflation because it is consistent, well known, published by a reputable independent organization and available free of charge. It is for these reasons that many municipal governments use the CPI to measure their inflation. However, the expenditure profiles of municipal governments are much different than the expenditure profile of an average Canadian consumer.

The average consumer spends money on food, housing, clothing, utilities and transportation, among other things. Municipal governments, on the other hand, build roads and pools, buy trees and buses and employ planners and firefighters. The CPI does not reflect the purchasing patterns of municipal governments and, thus, is not an accurate indicator of the inflationary pressures they face. To account for their unique expenditure profiles, several municipalities have opted to develop their own Municipal Price Indices.

⁵ Source: Statistics Canada. Table 326-0031 - Basket Weights of the Consumer Price Index.

4.0 Background to the Municipal Price Index

The concept of a Municipal Price Index (MPI) originated in 1978 when *American City and County* began publishing what they call a Municipal Cost Index (MCI). The MCI is designed to estimate the inflation rate of the costs of municipal service provision. The MCI is a composite index—a weighted average of more detailed price indices—consisting of the Consumer Price Index, the Producer Price Index and the U.S. Department of Commerce's composite Construction Cost Indices.⁶

Using the *American City and County* price index as a foundation, several Canadian municipalities have developed their own MPIs. By tailoring an MPI to match a municipal government's expenditure profile, a municipal government is better able to monitor and react to its unique inflationary circumstances. Calgary, Ottawa, Halifax, Waterloo, Strathcona County and St. Albert have all developed an MPI.

The City of Edmonton decided to develop an MPI as part of the administration's performance measurement program. An MPI can be used by the City of Edmonton in the following ways:

1. To measure the increase in overall municipal expenditures attributed to inflation.
2. To allow managers to more closely monitor the increase in spending by expenditure category, thus making inflationary price increases or decreases more visible.
3. To provide an indication of the historical, current and future direction of prices relative to municipal expenditures.
4. To explain increased expenditures attributed to inflation when submitting annual budgets.

⁶ American City and County: americancityandcounty.com

5.0 Methodology

Of all the Municipal Price Indices (MPIs) surveyed, the City of Calgary maintains an MPI most applicable to Edmonton. In several cases, other municipal governments have adopted Calgary's methodology when developing their own MPIs. Following the methodology employed by the City of Calgary, constructing the MPI consists of two parts: 1) determining the weights of expenditure categories within the City's operating budget and 2) determining the appropriate inflation factor for each expenditure category. Once the index has been collated with these data, municipal inflation can be calculated by summing every product of weight and inflation factor.

5.1 Expenditure Categories and Weights

The City of Edmonton's 2009 operating budget was analyzed to determine the expenditure categories and their respective weights in the development of the MPI. Items in the budget with similar inflationary pressures were grouped into broad expenditure categories. A total of 17 expenditure categories were formed. The weight of each category was assigned based on the percentage of the 2009 operating budget allocated to that category.

At that time, it was recommended that expenditure category weights be updated every five years. If the expenditure category weights are adjusted too frequently, year-to-year inflation rates become incomparable to one another.

The expenditure category weights were last updated while compiling the 2014 MPI to reflect the City's 2014 operating budget. Table 1 shows the updated weights for each expenditure category based on the 2014 operating budget.

The most heavily weighted expenditure categories—the categories that comprise the largest share of the 2014 operating budget—are wages and salaries (43.44%), employee benefits (11.48%) and contract services (9.77%).

Table 1: Expenditure Categories and Weights⁷

No.	Expenditure Category	Weight
1	Wages & Salaries	43.44%
2	Employee Benefits	11.48%
3	Equipment (Vehicles & Computers)	3.38%
4	Fuel	1.83%
5	Materials	3.82%
6	Natural Gas	0.40%
7	Utilities Total	2.29%
8	External Space	0.98%
9	Grants & Board Requisition	1.76%
10	Land Cost	5.53%
11	Tax Adjustments & Concessions	0.44%
12	Other Expenses	6.08%
13	Other Financing	0.04%
14	Travel & Training	0.52%
15	Contract Services	9.77%
16	Professional Services	1.20%
17	Debt Service Total	7.04%
	Total	100.0%

For illustrative purposes, Figure 2 further aggregates the 17 expenditure categories into seven even broader categories. As can be seen, over half of the City's annual operating budget is allocated to wages, salaries and employee benefits.

Figure 2: Expenditure Categories and Weights

⁷ The following items in the 2014 budget were not included in any MPI expenditure category because they do not represent budget components that undergo typical price inflation: 1) interdepartmental services, 2) amortization, 3) pay as you go levy and 4) transfers to reserves.

5.2 Inflation Factors

The next step in constructing the Municipal Price Index (MPI) is to assign an appropriate inflation factor to each expenditure category following the assignment of a weight to that category. The inflation factors assigned to each expenditure category are based on internal City of Edmonton sources, as well as several external sources. It is recommended that inflation factors be updated annually.⁸ Doing so will ensure each year's MPI calculation is congruent with the inflationary pressures facing the operating budget for that year.

It is important to match an appropriate inflation factor to each expenditure category. For example, the Conference Board of Canada's crude oil price forecast is an appropriate inflation factor for the expenditure category labelled "Fuel." Because the costs of crude oil and fuel will likely move in the same direction at approximately the same magnitude, this inflation factor was determined to be a good fit for the "Fuel" expenditure category. In other cases, where a suitable fit could not be identified, the CPI was used as a default inflation factor. A table of each expenditure category, as well as the data source and publisher for each inflation factor, is listed in Appendix 1.

For some expenditure categories, contracts that dictate the rate of inflation are in place. For these expenditure categories, inflation is determined by a contractual obligation to increase spending, irrespective of market forces. By far, the largest expenditure category is wages and salaries, which accounts for 43.44% of the City's operating budget. For 2010–2015, the wages and salaries increases for the City of Edmonton employees are based on actual labour settlements that extend into the future. At the time of writing this report, some unions were still in negotiations for labour settlements. The Alberta industrial composite wage inflation forecast was used as a proxy for the years 2010 to 2015 for bargaining units where a settlement had not been reached.

5.3 Calculating Municipal Inflation

The calculation for the Municipal Price Index (MPI) is based on the average of expected price changes for each expenditure category weighted by their respective proportion of the operating budget spent on that category. The weights for each expenditure category indicate the importance of an item or group of items in the municipality's operating budget. Using weights to

⁸ Inflation factors should be updated during the month of February of each calendar year.

construct the MPI prevents overstating the influence of a given item in the municipal basket of goods and services. An MPI can, therefore, be calculated using the following equation:⁹

$$MPI = X_1(W_1 / W) + X_2(W_2 / W) + \dots + X_n(W_n / W) \quad [2]$$

where:

MPI = Municipal price index

X_n = Price change for expenditure category *n*

W_n = Total expense of expenditure category *n* in the operating budget

W = Total expense of the City's operating budget

W_n/W = Weight of expenditure category *n* in the City's operating budget

Equation [2] can be rewritten as:

$$MPI = \sum_{i=1..n} X_n(W_n / W) \quad [3]$$

Equation [3] produces a single inflation rate, which is the rate of cost increases facing the City of Edmonton's operating budget for the year being examined.

⁹ Walters, Patrick. 2009. *The City of Calgary Corporate Inflation Rate – 2003–2008: As measured by a municipal price index*. Corporate Economics. The City of Calgary.

6.0 The City of Edmonton Municipal Price Index

The Municipal Price Index (MPI) is updated annually, generally during the first half of the year. The update to the MPI involves revising the previous year's estimated MPI values to reflect *actual* inflation figures and updating the inflation factors for the current year and the next four years with newer forecast values. This report incorporates the revisions to the previously estimated 2015 MPI values to reflect the actual figures and updates to the MPI forecasts for the 2016–2020 period.

The City's municipal inflation fluctuated within the 2% and 4% range between 2010 and 2015. Historically, municipal inflation has been consistently higher than consumer inflation with the exception of 2014 when consumer inflation was higher than municipal inflation. The difference between the MPI and CPI has ranged between 0.70% and 2.59% between 2010 and 2015.

Actual municipal inflation came in at 1.39% in 2015, higher than the 0.44% estimated at the beginning of 2015. The consumer inflation stood at 1.22% in 2015, lower than the 1.84% estimated at the beginning of 2015.

Both the municipal and consumer inflation rates are estimated to trend upward to 1.91% and 1.84%, respectively, in 2016. The MPI is forecasted to continue trending upward primarily due to increasing oil and natural gas prices between 2017 and 2020. Edmonton's municipal inflation is estimated to be 2.55% in 2017, 2.78% in 2018, 2.89% in 2019 and 3.06% in 2020. Consumer inflation is estimated to range between 1.84% and 2.48% over the same period. Figure 3 shows the municipal price inflation and consumer price inflation from 2010 to 2020.

Figure 3: Municipal Price Inflation vs. Consumer Price Inflation

Table 2 (page 15) shows the City of Edmonton's actual and forecasted MPI from 2010 to 2020. The inflation factors for years 2010 to 2015 represent *actual* historical inflation rates experienced in each of the expenditure categories while those for years 2016 to 2020 are forecasted inflation rates that are expected over the current year and the next four years.¹⁰

¹⁰ The actual municipal inflation rates from 2008 to 2013 are re-estimated based on the updated weightings for each expenditure category based on the City's 2014 operating budget.

Table 2: City of Edmonton Municipal Price Index

No.	Expenditure Category	Weight	Inflators For Each Expenditure Category										
			Actual						Forecast				
			2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020

7.0 Critical Factors for Success

7.1 Use External Sources for Inflation Where Possible

Critics of the Municipal Price Index (MPI) argue that it can be a self-serving tool, particularly if used to justify tax increases. To alleviate this criticism, the MPI should be calculated by an independent body. The Canadian Federation of Municipalities is currently lobbying Statistics Canada to calculate and maintain MPIs for Canadian municipalities. So far, however, municipalities have been calculating these indices on their own. To mitigate the criticism that the MPI is a self-serving municipal indicator, it must be both transparent and, where possible, use external sources.

7.2 Continue to Refine the Calculation

The inflation factors should be routinely reviewed, and new values should be assigned when existing ones are deemed inappropriate. Additionally, all expenditure categories should be regularly reassessed to ensure that an appropriate level of homogeneity exists within each category. This approach ensures that correct inflation factors—ones that accurately reflect inflationary pressures—are assigned to each expenditure category.

8.0 Application of the Municipal Price Index

The Municipal Price Index (MPI) is a powerful tool that measures the inflationary pressures that municipal operational expenditures face. The MPI can also be used by the City of Edmonton in the following ways:

- to enable managers to more closely monitor the increase in spending by expenditure category, thus making inflationary price increases or decreases more visible;
- to provide an indication of historical, current and future direction of prices relative to municipal expenditures and
- to explain increased expenditures attributed to inflation when submitting annual operating budgets.

14	Travel & Training	CPI Forecast	Conference Board of Canada
15	Contract Services	Wage Inflation Forecast, Alberta: Industrial Composite	Conference Board of Canada
16	Professional Services	Wage Inflation Forecast, Alberta: Industrial Composite	Conference Board of Canada
17	Debt Service Total ¹⁶	Prime Lending Rate	Conference Board of Canada

¹¹ Inflation factors for 2010–2015 were derived from wage and salary settlements. The Alberta industrial composite wage inflation forecast was used as proxy for 2015–2019 where bargaining settlement information was missing.

¹² Inflation factors for 2010–2015 were derived from labour settlements. For 2016–2020, the Alberta wage inflation forecast was used as proxy.

¹³ The Utilities expenditure category consists of power, water, telephones, sewer and waste, but it is largely comprises power. The Electricity Power Price Index is currently used as the inflation factor for Utilities. Research on alternatives continues, and this inflation factor will be replaced if a more suitable one is found. The Conference Board of Canada made some revisions to the Electricity Power Price Index in early 2013 to align this index with the structural revisions made to the Canadian System of National Accounts by Statistics Canada. As a result, the historical series has changed from the one used in estimating the 2012 MPI.

¹⁴ The CPI forecast is currently used as the inflation factor for External Space. Research on alternatives continues, and this inflation factor will be replaced if a more suitable one is found.

¹⁵ Inflation factors for 2010–2015 were calculated using historical (2010–2015) average housing prices, taken from the Canadian Real Estate Association (CREA) database. The 2016 forecast of average housing price was taken from the REALTORS Association of Edmonton forecast, which was made available in a press release. The 2017–2020 forecasts do not yet exist, so CPI forecasts for these years were used as proxy. Research on a more suitable inflation factor is ongoing. If a better alternative is found for this expenditure category, the current inflation factors will be replaced.

¹⁶ The movements in financing costs are expected to follow movements in the prime lending rate. Hence, the prime lending rate was used as the inflation factor for debt services. Research on a more suitable inflation factor is ongoing. If a more suitable alternative is identified, it will be replaced.
